

3.Aim

To detect phishing emails by checking suspicious indicators in the sender's email address, subject, and email body.

Algorithm

1. Start the program.
2. Read the sender's email address.
3. Read the email subject.
4. Read the email body.
5. Check the sender for suspicious domains or invalid format.
6. Search the subject and body for suspicious keywords.
7. Calculate the phishing score.
8. If the score exceeds the threshold, display **"Phishing Email Detected."**
9. Otherwise, display **"Email Seems Safe."**
10. Stop the program.

Code

```
def detect_phishing(sender, subject, body):  
    suspicious_keywords = ["urgent", "win", "free", "click", "password", "bank"]  
  
    score = 0  
  
    # Check sender  
    if "@" not in sender or sender.endswith(".ru"):  
        score += 1  
  
    # Check subject  
    for word in suspicious_keywords:  
        if word.lower() in subject.lower():  
            score += 1
```

```
# Check body

for word in suspicious_keywords:

    if word.lower() in body.lower():

        score += 1

if score >= 2:

    print(" ⚠️ Phishing Email Detected")
else:

    print("✅ Email Seems Safe")
```

Example

```
detect_phishing(
    "fakebank@secure.ru",
    "URGENT! Verify your account",
    "Click here to update your password"
)
```

Output

⚠️ Phishing Email Detected
