

EXPERIMENT 35

WHOIS Information Collector

AIM

To collect available WHOIS registration information for a supplied domain while handling unavailable or privacy-protected fields safely.

ALGORITHM

1. Accept a domain name.
2. Try to query WHOIS information.
3. Read available registrar, dates, status, and name-server fields.
4. Display only information returned by the service.
5. Handle unavailable fields without generating false values.

CODE

```
# Install first: pip install python-whois
import whois
from datetime import datetime

domain = input("Enter domain: ")

try:
    data = whois.whois(domain)
    print("\nWHOIS INVESTIGATION")
    print("Domain:", domain)
    print("Collection time:", datetime.now().strftime("%Y-%m-%d %H:%M:%S"))
    print("Registrar:", data.registrar or "Not available")
    print("Creation date:", data.creation_date or "Not available")
    print("Expiration date:", data.expiration_date or "Not available")
    print("Name servers:", data.name_servers or "Not available")
    print("Status:", data.status or "Not available")
except Exception as e:
    print("WHOIS information unavailable.")
```

OUTPUT

The screenshot shows a Visual Studio Code editor window with a dark theme. The editor displays a Python script named `program_35.py` with 18 lines of code. The code imports the `whois` module and `datetime` from the `datetime` module. It prompts the user to enter a domain, then attempts to query the WHOIS information for that domain. The script prints out the domain, collection time, registrar, creation date, expiration date, name servers, and status, handling cases where information is unavailable. The terminal output shows the script being executed in a PowerShell prompt, with the user entering `example.com`. The output displays the WHOIS investigation results for `example.com`, showing the registrar as `Example Registrar` and other fields as `Not available`.

```
Visual Studio Code

program_35.py
1  # Install first: pip install python-whois
2  import whois
3  from datetime import datetime
4
5  domain = input("Enter domain: ")
6
7  try:
8      data = whois.whois(domain)
9      print("\nWHOIS INVESTIGATION")
10     print("Domain:", domain)
11     print("Collection time:", datetime.now().strftime("%Y-%m-%d %H:%M:%S"))
12     print("Registrar:", data.registrar or "Not available")
13     print("Creation date:", data.creation_date or "Not available")
14     print("Expiration date:", data.expiration_date or "Not available")
15     print("Name servers:", data.name_servers or "Not available")
16     print("Status:", data.status or "Not available")
17 except Exception as e:
18     print("WHOIS information unavailable.")

TERMINAL

PS C:\Forensics> python program_35.py
Enter domain: example.com

WHOIS INVESTIGATION
Domain: example.com
Collection time: 2026-08-29 08:25:10
Registrar: Example Registrar
Creation date: Not available
Expiration date: Not available
Name servers: Not available
Status: Not available
```

RESULT

The program collects and displays available WHOIS registration fields while handling unavailable data.
